(54) Polymeric acrylic prosthesis.

(57) This invention relates to implantable porous prostheses for use as bone or hard tissue replacements anywhere in the body. The porous implants comprise loose, individual polymeric particles of a specified size, coated with a hydrophilic material and barium sulfate particles. The prostheses are biologically compatible in the body and promote bone and tissue ingrowth and attachment. This invention also relates to a method for producing the novel prosthetic devices disclosed herein.

EP 0 089 782 A1

POLYMERIC ACRYLIC PROSTHESIS

TECHNICAL FIELD

5 This invention relates to prostheses for use as
bone or hard tissue replacements in any part of the body.
More particularly, it discloses porous implants which are
biologically compatible in the body and promote bone and
tissue ingrowth and attachment. This invention also
10 relates to a method for producing the novel prosthetic
devices disclosed herein.

BACKGROUND ART

15 In cases where an entire tooth/root, a section of
bone or any hard tissue structure or defect must be
replaced or repaired, biological compatibility and
adequate ingrowth and attachment of surrounding body
tissue and bone must be assured.

20 U.S. patent application No. 214,572, filed
December 8, 1980, to Bruins et al. and assigned to Medical
Biological Sciences, Inc., the assignee herein, approaches
these problems of compatibility and tissue ingrowth by
25 providing prosthetic devices comprising selected-sized
polymethylmethacrylate (PMMA) beads modified with small
amounts of barium sulfate and coated with and physically
bonded together by means of a polymerized hydroxyethyl
methacrylate (PHEMA) coating. The resulting bonds between
30 the PHEMA coated PMMA particles provide a basic foundation
for porous implants having exceptional strength. Adequate
bone and tissue ingrowth is insured by the use of the
hydrophilic PHEMA coating which is wetted by the body
fluids.

35

SUMMARY OF THE INVENTION

5 The present invention provides a prosthesis comprising a conglomeration of modified PMMA beads which are not, initially, bonded together. Specifically, "modified" PMMA beads according to the invention are described as loose, individual PMMA beads coated with PHEMA and further modified with barium sulfate for x-ray identification.

10

The loose, individual modified PMMA beads may be inserted into areas of bone defects, such as cavities, or packed into any hard tissue part of the body in which repair, reconstruction or replacement is indicated. Areas where the loose, individual modified PMMA beads may be used include, for example, the third molar socket where no replacement molar is desired; furcations or bony recessions between adjacent teeth roots and infra-bony pockets caused by gum and bone disease. Non-oral applications include: fracture healing, bone cancer replacement, bony buildup in plastic surgery, filling of defective bone areas and replacement of metal implants, as well as replacement of any failing metal implants.

20

25

DETAILED DESCRIPTION OF THE INVENTION

The prosthesis of this invention comprises a conglomeration of modified PMMA beads which, in individual, loose form, may, initially, be packed into cavities or other areas of hard tissue defect or disease by means of a dental tool such as, for example, the type used to transfer silver amalgam. When a void in a hard tissue area is completely filled with the loose, individual modified PMMA beads, the surrounding soft tissue is then sutured over the beads to completely

30

35

enclose them. Once enclosed, the beads come into contact with each other, forming pores that are readily wettable by blood and body fluids. In this way, bone growth is promoted and bone recession prevented. As the healing
5 process progresses, ingrowth of surrounding bone and/or tissue throughout the interstices of the packed beads leads to the formation of a prosthesis comprising a conglomeration of the modified PMMA beads.

10 Loose, non-bonded PMMA beads coated with PHEMA and modified with small particles of barium sulfate are produced in a process similar to that disclosed in the applicants' patent application No. 214,572, filed December 8, 1980, which is herewith incorporated by reference. In
15 order to prevent bonding of the PMMA beads, the relative barium sulfate content of the implants is increased, while the amount of PHEMA is decreased and pressure avoided. Any clumps formed by the coated PMMA particles are broken up by physical means, such as a mortar and pestle.

20 The loose, non-bonded modified PMMA beads comprising the hard tissue implants of this invention are produced according to the following method. PMMA beads are thoroughly mixed with between about 10 and 20% by
25 volume, preferably 10%, and between about 21.5 and 43% by weight of .7 micron - or less than 1 micron - particle-size barium sulfate. Preferably, the size of the PMMA beads is chosen with a view towards the development of pore sizes that promote bone growth. Under various
30 embodiments of the invention, the PMMA beads may be about the 20 to 24 mesh size (particle diameters between about 700 and 840 microns) or about the 24 to 30 mesh size (particle diameters between about 590 and 700 microns) which are most easily transferred and packed into a void
35 in hard tissue areas, and which form a pore size which

promotes bone growth. The PMMA may contain small amounts of a plasticizer or a comonomer.

Between about four and seven percent, preferably
5 five percent by weight (based on the PMMA) of monomeric hydroxyethyl methacrylate (HEMA) is then added to the PMMA bead-barium sulfate mixture and the total mixture is then thoroughly mixed and combined to effect a uniform coating of the PMMA beads. The HEMA has a high grade of purity -
10 about 98.4% minimum and is lightly inhibited from polymerizing by trace amounts of an inhibitor such as the methyl ether of hydroquinone (MEHQ). The HEMA is preferably modified by the addition of a cross-linking agent such as triethyleneglycol dimethacrylate, which
15 comprises between about 1 and 5% of the HEMA, preferably 5%.

The mixed PMMA beads are subsequently heated while in a thin layer of about 1/16" to 1/8" in thickness
20 in a silicone rubber mold or on a non-polar surface such as Teflon, polyethylene or polypropylene, that does not heat up in the alternating field and whose surface acts as a release agent. The heat treatment is carried out in a dielectric oven such as a Model MBS-1, manufactured by
25 W.T. Rose and Associates of Troy, New York, until most of the hydroxyethyl methacrylate is polymerized. The heating step is, for example, about 1 1/2 minutes in duration when the upper electrode is in a position 1/4" above the top of the beads. The PMMA beads are then allowed to cool to an
30 ambient temperature between about 70° to 80°F and any clumps are broken up using a mortar and pestle and subsequently by screening.

Since the resulting modified PMMA beads may
35 contain residual amounts of monomeric HEMA, the beads are

then boiled in water for about 2 to 3 minutes in order to extract any remaining monomer. The PMMA beads are then spread out and air dried, or force dried under temperatures that are not high enough to cause melting.

5

The loose, non-bonded modified PMMA beads have a water-wettable PHEMA coating into which the barium sulfate particles are imbedded. All of the barium sulfate is attached to the PMMA beads and thus there are no free particles of barium sulfate remaining. The barium sulfate must be present in an amount to substantially prevent bonding between the PMMA particles. Therefore, if the amount of PHEMA coating is increased, a corresponding increase in the amount of barium sulfate used is required.

15

When the PMMA beads are to be packed into voids in hard tissue areas, it is advantageous that the PHEMA coating is wetted and swollen by water so that the beads become slightly adherent and can be more readily handled in clumps by a means of a dental tool, such as, for example, the type used to transfer silver amalgam.

Bone surfaces which will be adjacent to the prosthesis are advantageously pretreated in various ways. Preferably, any tartar or debris on the bone surface, as well as all diseased bone adjacent to the prosthesis should be removed. This may be accomplished by using, for example, a round dental burr. In oral applications, it is also desirable to remove any diseased bone, as well as all the tartar and debris on the tooth roots adjacent to the bone defect, by scaling and curettaging the root surfaces with either a periodontal instrument or an ultrasonic scaler. The cleaned root surface is then treated with a mild acid solution such as, for example, a 50% aqueous solution of citric acid or phosphoric acid, for about two

35

minutes, followed by rinsing with water. The mild acid treatment serves to collagenize the root and thus promote reattachment.

5 It is understood that the foregoing detailed description is provided merely by way of illustration and that several modifications may be made therein without departing from the disclosed invention.

CLAIMS

We Claim:

5 1. A packing material for forming in vivo
prothetic implants for hard tissue, the packing material
comprising disjoint particles, each particle having an
inner core comprised of a biologically-compatible
polymeric material and having an outer coating generally
10 surrounding the inner core, the outer coating being
comprised of a biologically-compatible hydrophilic
polymeric material, each particle incorporating a
sufficient quantity of barium sulfate to render a
prothetic implant formed of a compacted mass of the
15 particles visible in an X-ray radiograph, the particles
being of a size to permit a mass of the disjoint particles
to be packed in a body cavity having at least one surface
comprised of a hard tissue to form a prothetic implant
for the hard tissue with interstices between compacted
20 particles of the prothetic implant forming pores into
which tissue can grow.

2. The packing material of claim 1 in which the
diameter of the particles is in the range of from about
25 590 microns to about 840 microns.

3. The packing material of claim 2 in which the
cores of the particles are composed of an acrylic
polymeric material.

30 4. The packing material of claim 3 in which the
cores of the particles are polymethylmethacrylate beads.

5. The packing material of claim 4 in which the
35 polymethylmethacrylate beads include a plasticizer.

6. The packing material of claim 3 in which the cores of the particles are composed of a copolymer of methylmethacrylate and a comonomer.

5

7. The packing material of claim 3 in which the hydrophilic polymeric material is a polymeric hydroxyethylmethacrylate.

10

8. The packing material of claim 7 in which the ratio of the weight of the polymeric hydroxyethylmethacrylate to the weight of the cores of the particles is in the range of from about 0.04 to about 0.07.

15

9. The packing material of claim 8 in which the polymeric hydroxyethylmethacrylate comprises a copolymer of monomeric hydroxyethylmethacrylate and a cross-linking agent.

20

10. The packing material of claim 9 in which the cross-linking agent is triethyleneglycol dimethacrylate.

25

11. The packing material of claim 10 in which the ratio of the weight of the triethyleneglycol dimethacrylate to the weight of the monomeric hydroxyethylmethacrylate is in the range of from about 0.01 to about 0.05.

30

12. The packing material of claim 7 in which the barium sulfate is located in the coating of hydrophilic polymeric material.

35

13. The packing material of claim 12 in which the ratio of the weight of the barium sulfate to the weight of the cores of the particles is in the range of

from about 0.25 to about 0.43.

14. The packing material of claim 13 in which the barium sulfate is in the form of particles having a diameter of less than about one micron.

15. A process for producing a porous implantable prosthesis comprising a conglomeration of loose, individual, modified polymethylmethacrylate beads including the steps of:

a) mixing polymethylmethacrylate beads with between about 10 and 20% by volume or between about 21.5 and 43% by weight of less than one micron particle-sized barium sulfate;

b) adding between about 4 and 7% by weight (of the polymethylmethacrylate beads) of monomeric hydroxyethyl methacrylate to the polymethylmethacrylate-barium sulfate mixture, and mixing said mixture to effect uniform coating of the PMMA beads;

c) heating the mixture produced in step (b) with a dielectric heater while in a thin layer of about 1/16" to 1/8" thickness in a silicone rubber mold or on a non-polar surface until most of the hydroxyethyl methacrylate is polymerized;

d) cooling the mixture to an ambient temperature between about 70 and about 80°F.;

e) breaking up any clumps in the mixture;

f) boiling the mixture in water for about 2 to 3 minutes; and

g) spreading out the obtained modified polymethylmethacrylate beads for air-drying or force drying.
